

LCME, Russia, Saint-Petersburg, Problem 4.

Let's mark X,Z,Y edges of triangle T on the triangle ABC. $|AB|=q, |BC|=v, |AC|=t$ - lengths of sides of triangle ABC. $|AX|=x, |BY|=y, |CZ|=z \Rightarrow |BX|=q-x, |CY|=v-y, |AZ|=t-z$

We can count up area of triangle ABC and triangles, being included into it :

$$\begin{aligned} \text{area}(ABC) &= (1/2) * \sin(A) * q * t = (1/2) * \sin(B) * q * v = \\ &= (1/2) * \sin(C) * t * v \end{aligned}$$

$$\begin{aligned} \text{area}(AXZ) &= (1/2) * \sin(A) * x * (t-z) = \text{area}(ABC) * x * (t-z) / (q * t) = \\ &= \text{area}(ABC) * a * (1-c) \end{aligned}$$

$$\begin{aligned} \text{area}(BXY) &= (1/2) * \sin(B) * y * (q-x) = \text{area}(ABC) * y * (q-x) / (q * v) = \\ &= \text{area}(ABC) * b * (1-a) \end{aligned}$$

$$\begin{aligned} \text{area}(CYZ) &= (1/2) * \sin(C) * z * (v-y) = \text{area}(ABC) * z * (v-y) / (t * v) = \\ &= \text{area}(ABC) * c * (1-b) \end{aligned}$$

$$\begin{aligned} \text{area}(XYZ) &= \text{area}(ABC) - \text{area}(CYZ) - \text{area}(BXY) - \text{area}(AXZ) = \\ &= \text{area}(ABC) * (1 - (a+b+c) + (ab+ac+bc)) \end{aligned}$$

where a, b, c in $(0, 1)$ $a = x/q$, $b = y/v$, $c = z/t$

1.

(a) Let's prove, that $\text{area}(T) \geq \min \text{area}(T_1), \text{area}(T_2), \text{area}(T_3)$. Let it be false. It equals that $\text{area}(T) < \text{area}(T_1), \text{area}(T) < \text{area}(T_2), \text{area}(T) < \text{area}(T_3)$ at the same time. Let's write it as a formula.

$$\text{area}(ABC) * (1 - (a+b+c) + (ab+ac+bc)) < \text{area}(ABC) * a * (1-c)$$

$$\text{area}(ABC) * (1 - (a+b+c) + (ab+ac+bc)) < \text{area}(ABC) * b * (1-a)$$

$$\text{area}(ABC) * (1 - (a+b+c) + (ab+ac+bc)) < \text{area}(ABC) * c * (1-b)$$

Let's sum these inequality's and abbreviate on $\text{area}(ABC)$. We'll get a inequality:

$$3 * (1 - (a+b+c) + (ab+ac+bc)) < (a+b+c) - (ab+ac+bc) , \text{ which equals}$$

$$3/4 < (a+b+c) - (ab+ac+bc) . \text{ It will be true if } F(a) = (a+b+c) - (ab+ac+bc) - 3/4 \text{ would}$$

be positive on $(0, 1)$. $F'(a) = 1 - (b+c)$:

1) $b+c > 1$ $F'(a) < 0$. $\sup F(a) = \lim F(a) = b+c - b*c - 3/4$, where a goes to 0. Let's prove, that $\sup F(a) < 0$, i.e. for every b, c in $(0, 1)$ that $b+c > 1$, $b+c - b*c - 3/4 < 0$
 $b+c - b*c - 3/4 = g - b(g-b) - 3/4 = b^2 - b*g + g - 3/4$. $D = g^2 - 4(g - 3/4) < 0$ as $1 < g < 2$. Consequently $\sup F(a) > 0$ and $F(a) > 0$ for every a, b, c in $(0, 1)$. It means that

$area(T) \geq \min area(T_1), area(T_2), area(T_3)$ is true. Area(T) can be equal $\min\{area(T_1), area(T_2), area(T_3)\}$. For example, there is a triangle ABC with edges: $q=v=t; a=b=c=0.5$.

Inequality $area(T) \leq \max area(T_1), area(T_2), area(T_3)$ isn't always true. For example, there is a triangle ABC with equal edges $q=v=t$. Let's take sequence of $a, b, c: a_n=b_n=c_n=1/n$. We will get sequence of $area(T) = \sqrt{3/4} * a^2 - (1/2n) * a^2$. For n goes to endlessness, $area(T)$ goes to $area(ABC)$ and $\min\{area(T_1), area(T_2), area(T_3)\}$ goes to 0. So there is N , that for every $n > N$ $\sqrt{3/4} * a^2 - (1/2n) * a^2 > (1/2n) * a^2$ will be true.

2) $b+c = g \leq 1$ is similar.

(b) $height(T) \geq \min(height(T_1), height(T_2), height(T_3))$

$area(T) \geq \min area(T_1), area(T_2), area(T_3)$ is true. It means that there is a triangle T' from T_1, T_2, T_3 , for which $area(T) \geq area(T')$. But T and T' have one general side r . So $(1/2) * r * h(T) \geq (1/2) * r * h(T')$ is true $\Rightarrow h(T) \geq h(T')$ where $h(T)$ - height of $T, h(T')$ - height of T' to side r .
